AIRCRAFT CARBON DIOXIDE PROJECT

FINAL REPORT

1 JANUARY 196~~6~~<sup>7</sup>

Prepared By

Charles D. Keeling

Scripps Institution of Oceanography

La Jolla, California

A summary of measurements of samples of air collected at 300, 500,  
and 700 millibars by the Air Weather Service of the U. S. Air Force.

American Documentation Institute  
Document \_\_\_\_\_

National Science Foundation under grants Y/211/302, Y/901/132,  
G-8748, and G-19168.

### I. Introduction.

This report presents the results of a program to measure the concentration of atmospheric carbon dioxide over the Northern Pacific and Arctic Oceans from April 1958 through December 1961. Samples of air were collected by personnel of the 55th Weather Reconnaissance Squadron of the U. S. Air Force and were analyzed in the Scripps laboratory. The experimental method is described and the results interpreted in an article by Keeling, Harris, and Wilkins [1967].

The data were originally calculated as "index values" proportional to concentration. In 1959 it was established provisionally at Scripps that the true concentration (mixing ratio) in parts per million of dry air by volume (ppm) is given by the relationship:

$$\text{Manometric Concentration} = (C - 311.51) \frac{1.2188}{311.51} + 311.51$$

where C is the index value. This relationship has been used to determine all concentrations in this report. (It was also applied to other data obtained at Scripps and published by Pales and Keeling [1965], Brown and Keeling [1965], and Keeling et al. [1965].)

In Table 1 manometric concentrations are presented in chronological order of sampling. In Tables 2 - 6 work sheets are presented to show the basis for calculating summaries of the data which appear in Bolin and Keeling [1963] and in Keeling, Harris, and Wilkins [1968].

II. Full List of Data - Table 1.

This table presents the original data, listed in the order of date of sampling. The table supplies the flight name, observer, date, time of sampling, pressure height, geographic coordinates, and CO<sub>2</sub> concentration in ppm. These data are copied from a more detailed table on file at Scripps which lists in addition to these entries: index values, flask numbers, and sheet numbers of Flask Sample Laboratory Data Sheets. The latter constitute the original laboratory record of flask analyses at Scripps. The field information in columns 1 to 7 of Table 1 was copied from Aircraft Project Flight Data Sheets which list the information logged by an Air Force meteorologist on each flight. Figure 1 shows a facsimile of one of these sheets.

Column 2 identifies the sample-taker by a three-letter code as indicated below:

<u>Designation</u>	<u>Rank</u>	<u>Name</u>
BAN	Lt.	Banks
BOR	Lt.	Borton
BRE	Capt.	Brett
BUR	Capt.	Burwell
CAR	CWO	Carney
COM	Lt.	Commons
COO	Lt.	Cooley

STR	Lt.	Streeter
WIL	CWO	Williamson
YEL	Lt.	Yelton

A single asterisk in column 8 indicates that the sample is omitted from the compilations in Tables 2 - 5 because the sample was judged to have been contaminated during sampling. A double asterisk in the same column denotes additional samples omitted from compilations of Loon K flights labeled Revised in Table 3, as discussed in the next section.

### III. Zonal Monthly Averages - Tables 2 and 3

These tables show the basis for determining zonal monthly average concentrations of the 500 mb portions of Lark flights (Table 2) and 700 mb portions of Loon flights (Table 3) from the data of Table 1. In each Table the data have been sorted by month and zone. The zones are designated in the headings by specific latitudes which generally lie at the center of the zones. Thus the 12.5°N zone applies to data collected between 10.0° and 15.0°N, the 17.5°N zone between 15.1° and 20.0°N, and so on to 32.5°N. The 40.0°N zone, however, applies to data collected between 35.1 and 41.0°N. The 500 mb data for zone 40.0°N and all of the 700 mb data have been subdivided into subzones for purposes of computing adjustments as discussed below. In Table 2, zone 40.0°N, A refers to 35.1-39.4°N, B to 39.5-39.9°N, C to 40.0-41.0°N. In Table 3, A refers to the southern half, B to the northern half of each zone. Thus A under 12.5°N refers to 10.0-12.5°N, B to 12.6-15.0°N.

In the body of the Table under the name of the month are first listed the dates of all flights during that month and the number of flasks per zone for each flight. This information aids in locating the original data in Table 1. The average latitudes and dates, giving equal weight to each flask, are listed next. Average latitude and date adjustments in ppm

A single asterisk in column 8 indicates that the sample is omitted from the compilations in Tables 2 - 5 because the sample was judged to have been contaminated during sampling. A double asterisk in the same column denotes additional samples omitted from compilations of Loon K flights labeled Revised in Table 3, as discussed in the next section.

were determined as described in the next paragraph. The total number of flasks is the sum of the numbers for each flight. The (zonal monthly) average concentration gives equal weight to each flask. The concentration of each flask (before averaging) was referred to a datum of January 1960 by the formula:

$$\text{concentration (ppm)} = \text{manometric concentration (ppm)} - .72x(\Delta M/12)$$

where  $\Delta M$  is the number of months between the datum and the flight date, positive if the flight occurs after the datum.

The figure 0.72 is the average rate of increase in atmospheric  $\text{CO}_2$  in  $\text{ppm yr}^{-1}$  according to Bolin and Keeling [1963, p. 3901].

A more recent figure of Pales and Keeling [1965] is slightly lower (0.68 ppm), but the former value is used here so that the results of this report agree exactly with the former article.

The adjusted zonal monthly average concentrations which appear on the last line is the sum of the average concentration and both adjustments. The adjusted concentration is thus an estimate of the concentration expected to occur on the fifteenth of the month in question and at the specific plotting latitude listed in the headings.

To determine the adjustments, the (unadjusted) zonal monthly average concentrations of Table 2 and 3 were first plotted versus latitude and month, using the coordinates listed in the table headings ( $12.5^\circ\text{N}$ ,  $17.5^\circ\text{N}$ , etc.) as plotting

latitudes. Monthly averages of Stork and Ptarmigan flights, taken from Table 4, were added to the plots versus latitude, using as plotting latitudes the average latitude of each track: 78°N for Ptarmigan flights and 50°N for Stork flights. The Stork and Ptarmigan monthly average had been adjusted to apply to the 15th of each month beforehand (see Section IV) and were not altered when the other data were subsequently adjusted. On both the latitudinal and the monthly plots, smoothed curves were drawn with the constraint that the two modes of plotting be consistent. Preliminary latitude and date adjustments were then read from these smoothed curves and used to determine preliminary adjusted concentrations for the Lark and Loon flights. Revised curves were then drawn to conform to the adjusted concentrations. In a few cases the adjustments themselves were now altered to conform better with the revised curves and the whole process repeated. After the second revision, no further adjustments appeared necessary. The values in Tables 2 and 3 are consistent with the final version of the smoothed curves. Smoothed curves of concentration versus latitude for all months of the year and some of the smoothed curves versus season appear in Bolin and Keeling [1963]. The complete series versus season (including Ptarmigan and Stork flights, see Section IV) appears in this report as Figures 2 - 12. The

figures also show as solid dots, for the Lark and Loon flights, the adjusted zonal monthly average concentrations, and for the Ptarmigan and Stork flights, the unadjusted monthly averages.

The revised entries in Table 3 are consistent with a reevaluation of the Loon K flights by Pales and Keeling [1963] in which the authors rejected as contaminated several concentrations accepted in the compilation of Bolin and Keeling [1963]. Figures 9 - 12 reflect the revised values. The open and solid squares in Figures 3 - 14 of Bolin and Keeling [1963], plotted from the adjusted concentrations listed in Tables 2 to 4, however, include values in Table 3 without these revisions. The revisions do not significantly affect the smoothed latitudinal plots in Bolin and Keeling [1963], and corrected versions of the latitudinal plots have not been prepared for inclusion in this report.

#### IV. Flight Track Monthly Averages - Tables 4 and 5.

These tables give monthly summaries of data not included in Tables 2 and 3. The data are summarized for each track and pressure height but are not differentiated latitudinally within the tracks. For the Stork and Ptarmigan flights, the data show no systematic latitudinal variation within the tracks. For the other tracks the data are too few to investigate latitudinal

variations. The table includes those portions of Lark flights at 700 mb; those portions of Loon H flights at 500 mb; all Stork flights (at 500 mb); all Ptarmigan flights (500 and 700 mb). For Stork and Ptarmigan flights, date adjustments were read directly from smoothed curves based on the unadjusted track average concentrations versus month (Figures 2, 3, and 8). For Lark, 700 mb, the smoothed plot for Lark, 500 mb, 40-41°N, was used to estimate the adjustments.

The Loon H flights at 500 mb extended over such a wide range of latitudes that the date adjustments themselves had to be considered as a function of latitude. Table 5 lists individual adjustments for each latitude zone and weighted averages of these used to determine the adjusted values in Table 4. For zones centered at 27.5°N to 42.5°N, the individual adjustments were read from smoothed plots of Lark flights at 500 mb at 27.5°N, 32.5°N, 37.5°N, and 40.0°N. For zones centered 47.5°N to 57.5°N, they were read from the smoothed plots of the Stork flights.

No summary is given of 5 samples each collected on September 28, 1959 and April 7, 1960 on Lark U flights at 30,000 feet above sea level (300 mb). From Table 1 it may be seen that the data show no significant departures from data on the same flights at 500 mb.

Also, no summary is given of 6 samples collected on June 20, 1959 at 700 mb on a Stork G flight and 23 samples on two Lark I flights on April 6 and April 12, 1958. These last two flights, which initiated the aircraft sampling program, gave good data, but were on a track which cannot be readily compared with data from any other track. *Also, no summary is given of 10 samples on a special Stork flight over Canada, November 1, 1958.*

V. Smoothed Values of the CO<sub>2</sub> Concentration - Table 6.

In this table are copied values of concentration which correspond to the smoothed curves in Figures 2 - 12 for the fifteenth of each month. Values for latitudes 32.5°-78.0°N at 500 mb and 12.5°-17.5°N for 700 mb appear in Bolin and Keeling [1963, Table 3, p. 3911]. For latitudes 22.5°-27.5°N where data are available at both 500 and 700 mb, Bolin and Keeling prepared composite smoothed curves (see p. 3909 of their article) which yielded values lying between those at the separate levels. These composite values are not shown in Table 6, but appear in Table 3 of Bolin and Keeling [1963].

VI. Duplicate Samples - Table 7

This table lists the individual analyses, averages, and differences between analyses for nineteen samples run in duplicate during the course of the project. Samples were analyzed

in duplicate in the laboratory only when the first analysis was suspected to be in error. If we omit the measurements on Stork G at 2243, June 20, 1959, where the first analysis is clearly faulty, the average difference is 0.56 ppm. Individual differences are distributed rather evenly over the range 0.00 - 1.00 ppm. Duplicate analyses of samples collected in 5-liter flasks at the South Pole yield an average difference of only 0.2 ppm [Brown and Keeling, 1965, p. 6082]. These facts taken together suggest that the duplicate analyses of the aircraft samples, owing to the special selection of samples for rerun, did not reflect the average analytical error or the normal distribution of errors. Nevertheless, the errors, even if they were typical for the aircraft data, are not so large as to invalidate the conclusions reached by Keeling, Harris, and Wilkins [1968].

## FIGURES

Figure 1. Copy of an Aircraft Project Flight Data Sheet. The entries are information logged by the U. S. Air Force observer during flight.

Figures 2 - 12. The concentration of atmospheric CO<sub>2</sub> at various altitudes and latitudes as a function of month of the year. January through June (months 1 through 6) are plotted twice to reveal the seasonal pattern more fully. Solid dots are monthly average concentrations taken from Tables 2 - 4. In Figures 2, 3, and 8 unadjusted concentrations are plotted versus the average date of sampling as listed in Table 4. In Figures 4 - 7 and 9 - 12 adjusted values are plotted versus the fifteenth of the month. Solid curves are smoothed plots consistent with the latitudinal plots of Bolin and Keeling [1963, Figures 3 to 14, pp. 3903-3909]. Concentrations corresponding to the smoothed curves are given in Table 6.
